A typical SMES system includes three parts: superconducting coil, power conditioning system and cryogenically cooled refrigerator. Once the superconducting coil is energized, the current will not decay and the magnetic energy can be stored indefinitely. Superconducting magnetic energy storage (SMES) systems store energy in the magnetic field created by the flow of direct current in a superconducting coil that has been cryogenically cooled to a temperature below its superconducting critical temperature. This use of superconducting coils to store Superconducting magnetic energy storage (SMES) is the only energy storage technology that stores electric current. This flowing current generates a magnetic field, which is the means of energy storage. The current continues to loop continuously until it is needed and discharged. The superconducting Magnetic Energy Storage (SMES) is a highly efficient technology for storing power in a magnetic field created by the flow of direct current through a superconducting coil. SMES has fast energy response times, high efficiency, and many charge-discharge cycles. These qualities make SMES a good Superconducting energy storage systems store energy using the principles of superconductivity.
